What Are Polymers? Definition of Polymers

Polymers are large molecules composed of repeating structural units called monomers. These monomers are linked together through covalent bonds, forming long chains or three-dimensional networks. The term "polymer" originates from the Greek words "poly," meaning many, and "meros," meaning parts, reflecting their nature as many-unit molecules.

Types of Polymers

Polymers can be broadly classified into two categories:

- Natural Polymers:** Found naturally in the environment; examples include cellulose, proteins, and natural rubber.
- Synthetic Polymers:** Man-made through chemical processes; examples include polyethylene, polystyrene, and nylon.

Structure and Morphology of Polymers

Chain Structures

The physical properties of polymers are heavily influenced by their chain structures:

- Linear Polymers:** Monomers are linked end-to-end in a straight chain; typical examples are high-density polyethylene (HDPE).
- Branched Polymers:** Side chains branch off from the main chain, affecting density and melting point.
- Cross-linked Polymers:** Chains are interconnected through covalent bonds, forming a network; vulcanized rubber is a classic example.

Crystalline vs. Amorphous Regions

Polymers often contain both ordered (crystalline) and disordered (amorphous) regions:

- Crystalline Regions:** Ordered, tightly packed chains that influence strength and melting temperature.
